ROTARY ELECTRIC MACHINE, LINEAR MOTOR AND STATOR THEREOF

RECEIVED
OCT 17 2001
100800 MAIL ROOM

BACKGROUND OF THE INVENTION

The present invention relates to a rotary electric machine, a linear motor and a stator used for them.

In a stator of a ^{known} rotary electric machine [of which], armature windings are constructed ^{as} [in] a single layer distributed winding and ^{are} contained in a 3-phase-6-pole stator core having 36 slots, 2 slots per pole per phase, as shown in FIG. 8 and FIG. 9. The stator comprises a stator core 1 which has a back yoke portion 1a formed in a cylindrical shape; a plurality of tooth portions 1b projecting from ^{the} inner peripheral face of the back yoke portion 1a ^{and extending} toward the center; and [the] slots 2, each formed between ^{adjacent} [the] tooth portions 1b, and]. The plurality of armature windings 3 formed in a ring shape are arranged and contained in the slots 2 ^{with} [in] an arbitrary slot pitch.

The end coil portion of the armature winding 3 of the rotary electric machine is arranged in a form ^{such that it is} [of being] pushed and bent into a space near the side face of the back yoke portion 1b of the stator core 1.

In the stator having [the] armature windings 3, ^{that is} single layer wound ~~work~~ as described above, winding [work] is performed by initially ^{inserting} [containing] the windings U1, U2... in the outer peripheral (back bottom) side of the slot 2, and then by ^{inserting} [containing] the windings V1, V2... in the inner peripheral side of the slot 2, and finally by ^{inserting} [containing] the windings

W1, W2... in the innermost peripheral side of the slot 2
 (therein, the reference character attached to individual
 windings [of] U, V, W ^{represents} [express] the windings for U-phase, V-
 phase and W-phase, respectively). In the winding ^{process} ~~(work)~~, the
 5 individual coil end portions of the windings are arranged
 in the side face of the back yoke portion 1a of the stator
 core 1, and the coil end portions of the windings W1, W2...
 finally ^{insulated} [contained] are arranged onto the upper side of the
 coil end portions of the windings U1, U2..., W1, W2... for ^{the}
 10 V-phase and W-phase.

In the coil end portions of the windings in the side
 face of the back yoke portion 1a of the stator core 1, the
 height (dimension of the projected portion) H2 of the coil
 end portion becomes high, because the end portions are
 15 ^{arranged with} [overlapped over] ^{overlapped} one phase on the other phase, as shown in
 FIG. 10 (b).

Therefore, the axial dimension L2b of the stator,
 that is, the sum of the projected dimension H2 of the coil
 end portions and the ^{in the drawing} thickness dimension L2a of the stator
 20 core 1 becomes large. ^{represents} [Therein], the reference character 4
 [indicated] a rotor shaft.

In a linear motor, this means that the width
 dimension of the linear motor becomes large.

25 SUMMARY OF THE INVENTION

An object of the present invention is to reduce (an) ^{the}
 axial dimension or [a] width dimension of a stator by

reducing the projected dimension of the end coil portions of the windings contained in the stator core.

Another object of the present invention is to further reduce the wiring work cost and the material cost.

5 The present invention is characterized by a stator comprising a stator core having an even number of slots per pole per phase; and armature windings contained in the slots, the armature windings being wound ^{as} ~~in~~ ^{in this stator,} a single layer distributed winding, wherein one of the slots arranged
10 between two (of the) slots containing a first armature winding contains a second armature winding for a phase different from ^{the} (a) phase of the first armature winding ^{the} and; one of the slots arranged between (the) two of slots containing the first armature winding contains a third
15 armature winding for a phase equal to the phase of the second armature winding; and, one of the second armature winding and the third armature winding is arranged in a coil end portion in an outer peripheral side of the first armature winding, and the other is arranged in an inner
20 peripheral side of the first armature winding.

Further, the stator is characterized by ^{the fact} that (the) ^{it} (stator) is constructed by partially performing winding [work] of the armature windings ^{on} (to) a plurality of divided cores formed by laminating segments stamped in a sector ^{shape}; and then
25 assembling the plurality of divided cores into a cylindrical shape and ^{arranging} (containing) the armature windings, ^{to} spread ~~over~~ over the divided cores into the individual slots.

Further, the stator is characterized by ^{the fact} that an axial dimension of the stator, including the stator core and the coil end portions, is reduced by arranging the coil end portions in a space near a side face of a back yoke portion.

Furthermore, a rotary electric machine is constructed using the stator described above and a rotor which is held so as to be arranged opposite to the stator. A linear motor is constructed using the stator described above and a mover which is held so as to be arranged opposite to the stator.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

A rotary electric machine or a linear motor in accordance with the present invention comprises a stator having armature windings and a movable part, such as a rotor or a mover, held so as to be arranged opposite to the stator, though the rotary electric machine or the linear motor is not illustrated ^{in the} [as a] drawing in the present ^{application} [specification]. The movable part comprises secondary electric conductors in ^{the} [a] case of an induction motor or magnetic poles in ^{the} [a] case of ^a synchronous motor.

In a machine performing speed control or position control, electric power is supplied to the armature windings using an inverter circuit.

The present invention characterizes the stator in

such a rotary electric machine or a linear motor, and embodiments of the stator will be described below, ^{with reference} [referring] to the ^{accompanying} [accompanied] drawings.

5 (First Embodiment)

FIG. 1 is a schematic ^{diagram} [view] showing the side face of a stator ^{representing} [in] a first embodiment of a rotary electric machine in accordance with the present invention. FIG. 2 is a wiring diagram showing ^{the connection of} the armature windings to the stator in the rotary electric machine. ^{In this} [The] first embodiment of the ^{invention, the} [stator is a] stator ^{contains} [containing the] single layer distributed wound armature windings 3 in a 3-phase-6-pole stator core having 36 slots, 2 slots per pole per phase.

Referring to FIG. 1 and FIG. 2, ^{as in} [similarly to] a conventional stator core, the stator core 1 comprises a back yoke portion 1a formed in a cylindrical shape; a plurality of tooth portions 1b projecting from ^{the} inner peripheral face of the back yoke portion 1a ^{and extending} toward the center; and ^{adjacent} [the] slots 2, each formed between ^{the} tooth portions 1b.

The armature windings 3 are contained in ^{the} the individual slots 2 so as to be arranged in ^{the} order of the winding U1 for ^{the} U-phase, the winding W1 for ^{the} W-phase, the winding V1 for ^{the} V-phase, the winding U2 for ^{the} U-phase, the winding W2 for ^{the} W-phase, the winding V2 for ^{the} V-phase... (contained in order of U1, W1, V1, U2, W2, V2, ...Un, Wn, Vn).

This arrangement of the windings is formed as follows. The winding U1 to be ^{provided} [contained] first is ^{inserted} [contained] into the slots 2 of slot number 1 and slot number 6 of the stator core 1, and the winding W1 to be ^{provided} [contained] next is ^{inserted} [contained] into the slots 2 of slot number 3 and slot number 8 of the stator core 1. However, in regard to the ^{inserting} [containing] of the windings into the slots 2 of slot number 1 and slot number 3, the windings are ^{only} temporarily put ⁱⁿ [on] the slots. After that, the winding work is successively performed to ^{insert} [contain] the winding V1 into the slots of slot number 5 and slot number 10, the winding U2 into the slots of slot number 7 and slot number 12, the winding W2 into the slots of slot number 9 and slot number 14, the winding V2 into the slots of slot number 11 and slot number 16, until the winding ^{is inserted} U6. After the winding W6 and the winding V6 are contained in ~~the~~ the slots of slot number 2 and slot number 4, the winding U1 temporarily put [to be contained] into the slot of slot number 1 and the winding W1 temporarily put [to be contained] into the slot of slot number 3 are ^{so as} rearranged ^{inserted} [to be contained] into the corresponding slots 2.

When the dimension of the outer axial length of the rotary electric machine is shortened, the dimension of the above-mentioned projected coil end portions are decreased by pushing and bending the coil end portions of the windings 3 toward the space near the side face of the back yoke portion 1a of the stator core 1 like a file of

dominoes.

After all, the stator constructed as described above comprises a stator core having an even number of slots per pole per phase, and armature windings contained in the slots, the armature windings being wound ^{as} ~~in~~ ⁽ⁱⁿ⁾ a single layer distributed winding, wherein one of the slots arranged between two of the slots containing a first armature winding contains a second armature winding for a phase different from a phase of the first armature winding, and one of the slots arranged between ^{the} ~~(the)~~ two of ^{the} ~~the~~ slots containing the first armature winding contains a third armature winding for a phase equal to the phase of the second armature winding; and, one of the second armature winding and the third armature winding is arranged in a coil end portion in an outer peripheral side of the first armature winding, and the other is arranged in an inner peripheral side of the first armature winding. As ^{the} ~~(the)~~ result, the axial dimension of the stator can be reduced by decreasing the projected dimension of the coil end portions of the windings contained in the stator core.

(Second Embodiment)

FIG. 3 is a schematic ^{Diagram} ~~(view)~~ showing the side face of a ^{representing} stator, ^{second} ~~(in)~~ a ~~(first)~~ embodiment of a rotary electric machine in accordance with the present invention. FIG. 4 is a wiring diagram showing the ^{connection of the} single layer distributed wound armature windings to the stator in the rotary electric

In this machine. ^{invention, the} [The] second embodiment of the stator ^{contains} [is a stator] [containing the] single layer distributed wound armature windings in a 3-phase-6-pole stator core having 36 slots, 2 slots per pole per phase.

5 The shape of the stator core 1 is the same as the stator core 1 in the first embodiment. Further, the armature windings 3 are contained in ~~the~~ the individual slots 2 so as to be arranged in ^{the} order of the winding U1 for ^{the} U-phase, the winding W1 for ^{the} W-phase, the winding V1 for ^{the} V-phase, the winding U2 for ^{the} U-phase, the winding W2 for ^{the} W-phase, the winding V2 for ^{the} V-phase... (contained in ^{the} order of U1, W1, V1, U2, W2, V2, ...Un, Wn, Vn).

In this embodiment, the arrangement of the windings is formed as follows. The winding U1 to be ^{provided} [contained] first is normally ^{inserted} [contained] into the slots 2 of slot number 1 and slot number 6 of the stator core 1, and the winding W1 to be ^{provided} [contained] next is also normally ^{inserted} [contained] into the slots 2 of slot number 3 and slot number 8 of the stator core 1. After that, the winding work is successively performed to ^{insert} [contain] the winding V1 into the slots of slot number 5 and slot number 10, the winding U2 into the slots of slot number 7 and slot number 12, the winding W2 into the slots of slot number 9 and slot number 14, the winding V2 into the slots of slot number 11 and slot number 16, until ^{is inserted} [containing] the winding U6. The winding W6 and the winding V6 are ^{inserted} [contained] into the slots of slot number 2 and slot number 4 through the above portions of the coil end

portions of the winding U1 contained in the slot of slot number 1 and the winding W1 contained in the slot of slot number 3, respectively.

Similarly, in this stator, when the dimension of the outer axial length of the rotary electric machine is shortened, the dimension of the above-mentioned projected coil end portions are decreased by pushing and bending the coil end portions of the windings 3 toward the space near the side face of the back yoke portion 1a of the stator core 1 like a file of dominoes.

FIGS. 10(a) and 10(b) are *illustrations* *illustrating* [FIG. 10 is a] plan views [explaining] the axial dimension of the stator in the first and the second embodiments, which *illustrations are provided* *provide a comparison* *is illustrated* so as to *be compared* with the axial dimension of the conventional rotary electric machine.

Referring to FIG. 10 (a), the height H1 of the coil end portion can be formed *so as to be less* [lower] than the height H2 of the coil end portion of the stator *that is* wound using the conventional technology shown in FIG. 10 (b). Therefore, the total axial length L1b of the rotary electric machine, including the axial length L1a of the stator core and the heights of the coil end portions, can be reduced *(,)*; and, accordingly, the thickness of the rotary electric machine *reduced* can be *made thinner*.

25 (Third Embodiment)

Although the first and the second embodiments have *been* shown *by way of* *in which* (the) examples (that) the number of slots per pole and

per phase is two, in cases where the number of slots per pole and per phase is 4, 6, 8..., the same effect can be attained by similarly applying the present invention. As one [of the] example^a, ^adescription will be ^{given of} [made on] a rotary electric machine using a stator containing [the] armature windings in a 3-phase-4-pole stator core having 48 slots, 4 slots per pole per phase.

FIG. 5 is a schematic ^{diagram} [view] showing the side face of a stator ^{representing} [in] a third embodiment of a rotary electric machine in accordance with the present invention. The third embodiment of the stator has ^a [the] ^{such} structure that the stator contains [the] single layer distributed wound armature windings 3 in a 3-phase-4-pole stator core having 48 slots, 4 slots per pole per phase.

Each of the windings U1 to V4 for individual phases and poles comprises two coaxially wound ~~the~~ coils 3a, 3b, and the two coils 3a, 3b for each pole of the windings U1 to V4 are individually contained in ~~the~~ two slots adjacent to each other. That is, the two coils of the winding U1 for ^{the} U-phase are contained in the slots 2 of slot numbers 1, 2, 11 and 12, and the two coils of the winding W1 for ^{the} W-phase are contained in the slots 2 of slot numbers 5, 6, 15 and 16, and the two coils of the winding V1 for ^{the} V-phase are contained in the slots 2 of slot numbers 9, 10, 19 and 20 (and so forth).

Although the winding method employed in the second embodiment is employed in this embodiment, the winding

method of the first embodiment may be ^{employed as well} employed.

Similarly, when the dimension of the outer axial length of the rotary electric machine is shortened, the dimension of the above-mentioned projected coil end portions are decreased by pushing and bending the coil end portions of the windings 3 toward the space near the side face of the back yoke portion 1a of the stator core 1 like a file of dominoes.

10 (Fourth Embodiment)

In the fourth embodiment, the stator core is composed of a plurality of divided cores by laminating segments stamped in a ^{shape} sector, and then partially setting the windings to the divided cores through the winding method of the above-described embodiment, and, after that, assembling the plurality of divided cores into a cylindrical shape and ^{inserting} (containing) the armature windings spreading over the divided cores into the individual slots.

^{FIGs 6(a) and 6(b) are} (FIG. 6 is a) ^{diagrams} schematic (view) showing the side face of a stator in the fourth embodiment of a rotary electric machine in accordance with the present invention. The fourth embodiment of the stator comprises ^a [the] stator core which is composed of three divided core ^{sectors} 11, 12, 13 formed by laminating segments stamped in a ^{shape} sector. The windings ^{sectors} 30 are partially set to the divided core 11 to 13 through the winding method of the second embodiment, and after that the divided core ^{sectors} 11 to 13 are joined to form in a ^{core} a

cylindrical shape; and, at the same time, the armature windings 31, 32 spreading over the divided core^{sectors}, are ^{insulated} [contained] into the individual slots.

FIG. 6 (a) shows the state ^{in which} ~~(that)~~ windings ^{have} ~~(has)~~ been partially wound ~~to~~ to one of the sectorial divided cores 11. As the method of winding in this embodiment, the method of winding in the second embodiment is employed. The windings are similarly set to the other divided core^{sectors} 12 and 13.

FIG. 6 (b) shows the state of assembling ^{of} the three divided core^{sectors} 11 to 13 having ^{windings} partially set [windings ^{into} to] the cylindrical stator core 10. In regard to the method of ^{arranging} [containing] the windings 31 ^{to} spreading ~~over~~ over the divided portion and entering ~~into~~ into the slots 20 in the end portion of the adjacent divided core and the windings 32 ^{to} enter ~~into~~ into the slot 20 in the end portion of ^{its} [the] own divided core, there are two methods, that is, a method of ^{arranging} [containing] the winding by exchanging and a method of ^{arranging} [containing] the winding not by exchanging. Which method should be employed may be selected depending on a status of ^{the} work ~~place~~ place. In
 20 [the] other words, which method should be employed is determined by which winding arrangement is selected, the winding arrangement shown by the first embodiment or the winding arrangement shown by the second embodiment.

Since the winding work ^{applied} to the divided cores 11 to 13 formed by laminating the segments stamped in the sector can be performed in an open and wide work space, the workability is better than that of the winding work ^{applied} to the

stator core 10 of one-piece structure performed in a closed and narrow work place^(c); and, accordingly, [a] ratio of [constituting] the winding cross section in the slot (a share of the windings) can be increased. Further, since the

5 stator core 10 is constructed by assembling the divided ^{sectors} core 11 to 13, the sectorial segments composing each of the divided core ^{sectors} 11 to 13 can be stamped with a good yield to improve the use factor of the core material and to reduce the material cost.

10 Further, when the dimension of the outer axial length of the rotary electric machine is shortened, the dimension of the above-mentioned projected coil end portions are decreased by pushing and bending the coil end portions of the windings 3 toward the space near the side face of the

15 back yoke portion 1a of the stator core 1 like a file of dominoes.

(Fifth Embodiment)

The ^{structural arrangement of} [structure of arranging] the armature windings in

20 the stator in accordance with the present invention can be similarly applied to the stator in a linear motor. The fifth embodiment is ^{directed to} a stator in a linear motor, which ^{takes} [is] a ^{similar to that} form of expanding the cylindrical stator of the first embodiment of the rotary electric machine.

25 FIG. 7 is a schematic view showing the side face of the stator [in the fifth embodiment] of the linear motor in accordance with ^{the fifth embodiment of} the present invention.

Referring to FIG. 7, similar ~~to~~ to a conventional stator core, a stator core 41 comprises a back yoke portion 41a; a plurality of tooth portions 41b extending from the upper face of the back yoke 41a; and slots 50 formed
 5 between the tooth portions 41b.

The armature windings 60 are contained in ~~the~~ the individual slots 50 so as to be arranged in ^{the} order of the winding U1 for ^{the} U-phase, the winding W1 for ^{the} W-phase, the winding V1 for ^{the} V-phase, the winding U2 for ^{the} U-phase, the
 10 winding W2 for ^{the} W-phase, the winding V2 for ^{the} V-phase... (contained in order of U1, W1, V1, U2, W2, V2, ...Un, Wn, Vn). The arrangement of the windings 60 is similar to that of the first embodiment.

When the dimension of the outer axial length of the
 15 linear motor is shortened, the dimension of the above-mentioned projected coil end portions are decreased by pushing and bending the coil end portions of the windings 60 toward the space near the side face of the back yoke portion 41a of the stator core 41 like a file of dominoes.

20 According to the present invention, the dimension of the projected coil end portions in the axial direction or the width direction can be decreased, and, accordingly, the thickness of the rotary electric machine can be ^{reduced} made thin and the width of the linear motor can be decreased.

25 Further, by employing the divided core, the winding work can be improved and the use factor of the core material can be improved, and the work cost and the

material cost can be reduced.
